BIOS 526 Course Summary

1. Ordinary least squares (M1):

$$\operatorname{Cov} \mathbf{Y} = \sigma^2 \mathbf{I}$$
$$\hat{\boldsymbol{\beta}}^{OLS} = (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}' \mathbf{Y}$$

2. Generalized least squares (M4, slide 16) is a formulation for any given covariance matrix:

$$\operatorname{Cov} \mathbf{Y} = \mathbf{\Sigma}$$

$$\hat{\boldsymbol{\beta}}^{GLS} = (\mathbf{X}'\mathbf{\Sigma}^{-1}\mathbf{X})^{-1}\mathbf{X}'\mathbf{\Sigma}^{-1}\mathbf{Y}$$

- Need to know Σ .
- ullet In practice, we impose structure on Σ and estimate a statistical model, e.g., mixed models with Gaussian assumptions, GEE with Gaussian assumptions.
- 3. Linear mixed models (M2)
 - Random intercept:

$$y_{ij} = \mathbf{x}_i' \mathbf{\beta} + \theta_i + \epsilon_{ij}$$
$$\theta_i \stackrel{iid}{\sim} N(0, \tau^2)$$
$$\epsilon_{ij} \stackrel{iid}{\sim} N(0, \sigma^2)$$
$$\epsilon_{ij} \perp \mathbf{\mu} \theta_i$$

- Also see random slopes and hierarchical models
- 4. Generalized linear models (M3 part I):

$$y_i \stackrel{ind}{\sim} P(Y_i | \boldsymbol{x}_i' \boldsymbol{\beta})$$

$$g(E(Y_i)) = \boldsymbol{x}_i'\boldsymbol{\beta}$$

• logistic regression for 0, 1 response:

- Model:

$$y_i \stackrel{ind}{\sim} Bernoulli(E[Y_i])$$

$$\log \left\{ \frac{E[Y_i]}{1 - E[Y_i]} \right\} = \mathbf{x}_i' \mathbf{\beta}$$

- $\operatorname{Var}(Y_i) = E(Y_i) \{ 1 E(Y_i) \}.$
- Poisson regression for count data.
 - Model:

$$y_i \stackrel{ind}{\sim} Poisson(E[Y_i]),$$

 $\log \{E[Y_i]\} = \mathbf{x}_i' \boldsymbol{\beta}.$

- $\operatorname{Var}(Y_i) = E(Y_i).$
- Watch out for overdispersion, i.e., $Var(Y_i) > E(Y_i)$.
- 5. Generalized linear mixed models (M2, M3 part II):

Random intercept model:

$$y_{ij} \sim P(Y_{ij}|\boldsymbol{x}'_{ij}\boldsymbol{\beta} + \theta_i)$$

 $g\left\{E(y_{ij}|\theta_i)\right\} = \boldsymbol{x}'_{ij}\boldsymbol{\beta} + \theta_i$
 $\theta_i \stackrel{iid}{\sim} N(0, \tau^2)$

- Handle repeated measurements / longitudinal / clustered data.
- For Gaussian, interpretation of β not impacted by conditional versus marginal (the estimates of β from LMM and GEE are different but usually similar, in some cases GEE with exchangeable correlation structure and random intercept LMM have equivalent $\hat{\beta}$).
- For logistic, interpretation of β in GLMM (conditional model) is different from the interpretation in a GEE (the estimates of β from GLMM and GEE are different).
- For Poisson, the interpretation of β_1, \ldots, β_p in GLMM (conditional model) is the same as in the GEE due to a special property of the log link. The intercept changes, as the intercept in the marginal models includes $\tau^2/2$; see the R code.
- Use mixed models if interested in subject-specific predictions (shrinkage towards population effects).
- Can use if no overdispersion in logistic or Poisson, no heteroscedasticity in Gaussian.

6. Generalized estimating equations (M4):

$$y_{ij} \sim P(Y_{ij} | \mathbf{x}'_{ij} \boldsymbol{\beta})$$
$$g(E[Y_{ij}]) = \mathbf{x}'_{ij} \boldsymbol{\beta}$$
$$Cov(\mathbf{Y}_i) = \mathbf{D}_i^{1/2} \mathbf{R}(\alpha) \mathbf{D}_i^{1/2}$$

where $\mathbf{R}(\alpha)$ is the working correlation and \mathbf{D}_i is a diagonal matrix with diagonal elements equal to the variance determined by the likelihood.

- Handle repeated measurements / longitudinal / clustered data.
- Use robust standard errors.
- Use if heteroscedasticity and/or overdispersion (valid inference, unlike GLMM).
- Marginal inference (no random effects).
- 7. Generalized additive models (M5):

$$g(E(Y_i)) = \beta_0 + s_1(x_{i1}) + \dots + s_j(x_{ip})$$

- Handle non-linear effects.
- Can incorporate random effects for longitudinal / repeated measures / clustered data.
- Can generalize interactions from linear models to bivariate splines, e.g., $s(x_{i1}, x_{i2})$, i.e., 2D surfaces.
- Estimate $s(x_{ik})$ using either cross-validation or mixed model formulation of spline coefficients.
- 8. Bias-Variance Tradeoff (M5, part I, slides 33-43, M6, part II, slides 5-6)
 - $MSE(\hat{f}(x)) = Var(\hat{f}(x)) + Bias(\hat{f}(x))^2$
 - Fewer parameter: more bias, less variance
 - More parameters: less bias, more variance
 - Use cross-validation or generalized cross-validation to approximately minimize the MSE
- 9. Principal component analysis (M6 I): uses the singular value decomposition on standardized $N \times p$ data:

$$\mathbf{X}_{scaled} = \mathbf{U}\mathbf{D}\mathbf{V}'$$

- \bullet Lower dimensional representation using first q left eigenvectors.
- Principal component scores: $\mathbf{U}_{1:q}\mathbf{D}_{1:q}$,

- Can use in principal component regression when have issues with multicollinearity.
- 10. Ridge Regression (L2-norm regularization) (M5 part II, M6 part II):

$$\hat{\boldsymbol{\beta}}^{Ridge} = (\mathbf{X}'\mathbf{X} + \lambda \mathbf{I})^{-1}\mathbf{X}'\mathbf{Y}$$

- Regularization method with a nice closed form.
- Also extends to likelihoods (M6 part II):

$$\underset{\boldsymbol{\beta}}{\operatorname{argmin}} \quad -\sum_{i=1}^{n} \ell(y_i; \boldsymbol{x}_i' \boldsymbol{\beta}) + \lambda ||\boldsymbol{\beta}||_2^2.$$

- Can use when lots of covariates, p > n.
- Use for shrinking spline coefficients in GAMs (used in MGCV).
- 11. Lasso (L1-norm regularization) (M6 part II):

$$\hat{oldsymbol{eta}}^{Lasso} = \underset{oldsymbol{eta}}{\operatorname{argmin}} \quad -\sum_{i=1}^{n} \ell(y_i; oldsymbol{x}_i' oldsymbol{eta}) + \lambda ||oldsymbol{eta}||_1$$

- Regularization that results in variable selection by setting many coefficients equal to 0.
- 12. Elastic net (L1-norm and L2-norm regularization) (M6 part II):

$$\hat{\boldsymbol{\beta}}^{ElNet} = \underset{\boldsymbol{\beta}}{\operatorname{argmin}} \quad -\sum_{i=1}^{n} \ell(y_i; \boldsymbol{x}_i' \boldsymbol{\beta}) + \lambda \sum_{j=1}^{p} \left(\alpha |\beta_j| + \frac{(1-\alpha)}{2} \beta_j^2 \right).$$

- A good choice when predictors are correlated.
- Use for variable selection.
